Aims: Neuronal and non-neuronal bradykinin (BK) receptors regulate the contractility of the bladder urine outflow region. The current study investigates the role of BK receptors in the regulation of the smooth muscle contractility of the pig intravesical ureter. Methods: Western blot and immunohistochemistry were used to show the expression of BK B₁ and B₂ receptors and myographs for isometric force recordings. Results: B₂ receptor expression was consistently detected in the intravesical ureter urothelium and smooth muscle layer, B₁ expression was not detected where a strong B₂ immunoreactivity was observed within nerve fibers among smooth muscle bundles. On ureteral strips basal tone, BK induced concentration-dependent contractions, were potently reduced by extracellular Ca²⁺ removal and by B₂ receptor and voltage-gated Ca²⁺ (VOC) channel blockade. BK contraction did not change as a consequence of urothelium mechanical removal or cyclooxygenase and Rho-associated protein kinase inhibition. On 9,11-dideoxy-9α,11α-methanoepoxy prostaglandin F₂α, (U46619)-precontracted samples, under non-adrenergic non-cholinergic (NANC) and nitric oxide (NO)-independent NANC conditions, electrical field stimulation-elicited frequency-dependent relaxations which were reduced by B₂ receptor blockade. Kallidin, a B₁ receptor agonist, failed to increase preparation basal tension or to induce relaxation on U46619-induced tone. Conclusions: The present results suggest that BK produces contraction of pig intravesical ureter via smooth muscle B₂ receptors coupled to extracellular Ca²⁺ entry mainly via VOC (L-type) channels. Facilitatory neuronal B₂ receptors modulating NO-dependent or independent NANC inhibitory neurotransmission are also demonstrated. Neurourol. INTRODUCTION

Bradykinin (BK), a metabolite of the kallikrein–kinin system, is a potent mediator of inflammation, causing pain, vasodilation, increased vascular permeability, and smooth muscle contraction.¹² BK exerts its action via two receptor subtypes B₁ and B₂.³ BK shows a much higher affinity for the B₂ receptor, whereas the B₁ receptor exhibits greater selectivity for BK metabolites lacking the C-terminal Arg.³ BK immunoreactivity (IR) is present in afferent and efferent neurons innervating the bladder and urethra smooth muscle and in the urothelium, where BK exerts a wide range of biological actions including the ability to contract the detrusor smooth muscle, stimulate sensory nerves, and evoke the release of cyclooxygenase (COX) products.⁴–⁷ In the rat bladder, BK contraction is produced independently of phospholipase C involving L-type Ca²⁺ channels, as well as by rho-kinase and phospholipase A₂/COX dependent mechanisms.⁸ BK also modulates the human urothelial phenotype, accelerating stretch-induced ATP release, release of nerve growth factor, and TRPV1 channel expression. BK-induced changes in urethelial sensory function might contribute to bladder dysfunction.⁹ In the bladder neck, neuronal B₂ receptors modulate non-adrenergic non-cholinergic (NANC) inhibitory neurotransmission, whereas urothelial B₁ and muscle B₂ receptors produce relaxation and contraction, respectively, of smooth muscle.¹⁰ BK receptors have been proposed as therapeutic receptor targets for stress urinary incontinence, by increasing outlet resistance.¹¹ These receptors also play a key role in the pathogenesis of experimental cystitis and kallikrein–kinin system activation has been reported in bladders of patients suffering interstitial cystitis.¹²,¹³ Thus, BK, via B₂ receptors, is involved in the genesis of detrusor hyperreflexia during cyclophosphamide-induced cystitis favoring the development of bladder pain and increased urinary frequency.¹²,¹³

The ureterovesical junction plays an important role in both the active transport of urine bolus from ureter to bladder and the prevention of vesicoureteral reflux during bladder filling. The study of peptide receptors in the distal ureter might be useful to identify therapeutic targets to vesicoureteral reflux. In fact, angiotensin II receptor antagonists have been proposed to prevent renal fibrosis associated with reflux nephropathy. BK receptors play a pivotal role in the regulation of the bladder outflow region tension, no data exist, however, about their possible involvement in distal ureteral tone regulation. Therefore, the current study investigates the role of BK receptors on the pig intravesical ureter smooth muscle contractility.

**MATERIALS AND METHODS**

**Tissue Collection and Dissection**

Adult pigs of either sex with no lesions in their urinary tract were selected from the local slaughterhouse. Urinary bladders with attached ureters were removed immediately after the animals were sacrificed, and kept in chilled physiological saline solution (PSS) at 4°C. The adjacent connective and fatty tissues were removed with care, and longitudinal preparations (4–6 mm long and 2–3 mm wide) of the intravesical ureter, which is a ureteral segment located inside the bladder wall thickness formed by intramural and submucosal components, were dissected from the bladder.

**Western Blot**

Intravesical ureteral segments were homogenized in lysis buffer containing 10 mM Tris–HCl (pH 7.4), 1% SDS, 1 mM sodium vanadate, and 0.01% protease inhibitor cocktail (all from Sigma–Aldrich). Thirty-micrograms of protein were separated in a 15% polyacrylamide gel (SDS–PAGE) and transferred to a polyvinylidene fluoride (PVDF) membrane (BioRad laboratories, Madrid, Spain). All membranes were blocked in 5% non-fat dry milk for 1 hr at room temperature. For immunodetection, membranes were incubated overnight at 4°C with rabbit monoclonal anti-B1 or anti-B2 receptor antibodies (1:200, Santa Cruz Biotechnology, Inc., Heidelberg, Germany). The membranes were then washed in 0.05% Tween-20, incubated with a HRP-conjugated anti-rabbit secondary antibody (1:7,000, GE Healthcare Europe GmbH, Barcelona, Spain) for 1 hr at room temperature, and then washed and visualized by chemiluminescence (ECL advance-kit, GE Healthcare).

**Immunohistochemistry**

Intravesical ureter segments were fixed in 4% paraformaldehyde in 0.1 M phosphate buffer, pH 7.4 (PB), for 2–4 hr at 4°C, and subsequently placed in 30% sucrose in PB for cryoprotection. The tissue was embedded and frozen in OCT compound (Tissue-Tek®). Sakura Finetek, Europe B.V.), and stored at −80°C. Transversal sections 5 μm thick were obtained by means of a cryostat and pre-incubated in 10% normal goat serum in PB containing 0.3% Triton-X-100, for 2–3 hr. Then, sections were incubated with rabbit anti-B1 or anti-B2 receptor antibodies at 1:50 final concentration, plus a mouse anti-protein gene product 9.5 (anti-PGP 9.5) (Abcam, Cambridge, UK), as a neuronal marker, diluted 1:50, during 48 hrs at 4°C, washed and reacted with the secondary antibodies Alexa Fluor 594 goat–anti-rabbit (1:200 dilution) to detect B1 or B2 receptors and Alexa Fluor 488 goat–antimouse (1:200 dilution) to detect PGP 9.5, for 2 hrs at room temperature. The slides were covered with a specific mounting medium with DAPI (Invitrogen, Paisley, UK), which stains all cell nuclei. No immunoreactivity (IR) could be detected in sections incubated in the absence of the primary antiserum.

**Myographs for Isometric Force Recordings**

Ureteral strips 4–5 mm long and 2–3 mm wide were suspended horizontally with one end connected to an isometric transducer (Grass FT03C) and the other to a micrometer screw, in 5 ml organ baths containing PSS at 37°C gassed with carbogen (95% O2 and 5% CO2) to obtain a final pH of 7.4. The signal was continuously recorded on a polygraph (Graphpec MC6621). Passive tension of 2 g was applied to the strips and they were allowed to equilibrate for 60 min. The contractile ability of the strips was determined by exposing them to potassium rich (124 mM) PSS (KPSS). The effect induced by BK receptor agonists was studied on preparation basal tension as well as on 0.1 μM 9,11-dideoxy-9a,11α-methanooxyprostaglandin F2α (U46619)-induced contraction. A first control response curve to BK was obtained, the bath solution was then changed every 15 min for a period of 90 min, the preparations were incubated with the specific treatments for 30 min, and then a second cumulative contraction and/or relaxation curve was constructed. The concentration of the agents used was chosen on the basis of previous studies. Mechanical removal of the urothelium was performed by dissection under the microscope with a cold light source.

To investigate the role of extracellular Ca2+ entry, strips were washed three times and kept for 5 min in Ca2+-free PSS containing 0.1 mM EGTA, and then the solution was changed to Ca2+-free KPSS without EGTA. Under these conditions, contractions were obtained on basal tone elicited by sub-maximal BK doses in the absence or presence of extracellular Ca2+.

In electrical field stimulation (EFS) experiments, noradrenergic neurotransmission and muscarinic receptors were blocked by pre-incubation with guanethidine (10 μM) and atropine (1 μM), in the absence or presence of the NO synthase inhibitor Nω-nitro-L-arginine (L-NOARG, 100 μM), for 1 hr, replacing the solution every 20 min, and these drugs were present throughout the experiment. In U46619-precontracted strips, EFS was performed by delivering rectangular pulses (1 ms duration, 0.5–16 Hz, 20 s trains, with constant current output adjusted to 75 mA), at 4 min intervals, from a Cibertec CS20 stimulator (Barcelona, Spain). These EFS parameters have previously been used to elicit neurogenic relaxations in the intravesical ureter.

**Drugs and Solutions**

The following drugs were used: bradykinin (BK), HOE140, indomethacin, Lys-[Des-Arg9]bradykinin (kallidin), R829; 1-[2-(4-methoxyphenyl)-2-[3-(4-methoxyphenyl) propoxy]ethyl]-1H-imidazole hydrochloride (SKF96365); 9,11-dideoxy-9α,11α-methano epoxyprostaglandin F2α (U46619); and trans-4-[[(1R)-1-aminoethyl]-N-4-pyridinylcyclohexanecarboxamide dihydrochloride (Y27632) from Tocris (UK) and atropine, guanethidine, nifedipine, and Nω-nitro-L-arginine (L-NOARG) from Sigma. Indomethacin, nifedipine, and U46619 were dissolved in 96% ethanol. The other drugs were dissolved in distilled water. Preliminary experiments showed that these solvents, at their final concentrations, had no effect on the preparations contractility. The primary BK B1 or B2 receptor antagonists were from Santa Cruz Biotechnology and PGP 9.5 was from Abcam. The secondary antibodies were from Invitrogen.

*Neuromurology and Urodynamics* DOI 10.1002/nau
The composition of PSS was (mM): NaCl 119, KCl 4.7, KH2PO4 1.18, MgSO4 1.17, CaCl2 1.5, ethylenediaminetetraacetic acid 0.027, and glucose 11. The solution was kept at 37°C and continuously gassed with carbogen to maintain pH at 7.4. KPSS was PSS with KCl exchanged for NaCl on an equimolar basis. Stock solutions were prepared daily in distilled water.

Calculations and Statistics

Contractions to BK receptor agonists are expressed as a percentage of the contraction induced by KPSS (124 mM). Relaxations to EFS are expressed as a reversal percentage of the 0.1 μM U46619-induced tone. For each concentration–response curve (CRC) the concentration required to give half maximal response (EC50) was estimated by computerized non-linear regression analysis (GraphPad Prism, GraphPad Software, Inc, La Jolla, CA). The potency and maximal responses to agonists are expressed in terms of pD2 and Emax, respectively. pD2 is defined as the negative logarithm of EC50 (pD2 = -log EC50). Results are expressed as mean ± SEM of n (number of preparations, 1–2 strips per animal). Statistical significance of the differences was studied by Student’s t-test for paired observations and by analysis of variance (ANOVA) and a posteriori Bonferroni method for multiple comparisons. The differences were considered significant with a probability level of P < 0.05.

RESULTS

Expression of the BK B1 and B2 Receptors

In Western blots of intravesical ureter membranes, antibodies directed against the BK B2 recognized a specific band located at approximately 43 kDa, the expected molecular weight for the B2 receptor, both in smooth muscle and urothelium (Fig. 1A). Moreover, BK receptor subtype antibodies combined with the neuronal marker PGP 9.5 showed B2 receptor expression within nerve fibers distributed in the smooth muscle layer of the intravesical ureter, running parallel to the smooth muscle bundles (n = 5) (Fig. 1B–I). B1 receptor expression was not detected.

Functional Studies

Ureteral strips were allowed to equilibrate to a passive tension of 1.9 ± 0.1 g (n = 168 preparations from 84 pigs). Under these conditions KPSS produced a contraction above the basal tension of 2.4 ± 0.2 g (n = 168).

Effect of Urothelium Mechanical Removal and of B1 and B2 Receptor and COX Pathway Blockade on BK Contractions

On preparation basal tone, BK (0.1 nM–30 μM) produced concentration-dependent contractions (pD2 and Emax values being 6.3 ± 0.2 and 69.3 ± 3%), which were largely reduced by HOE140 (0.1 μM), a B2 receptor selective antagonist (n = 9) (Fig. 2A and B). These contractions, however, were not modified by urothelium mechanical removal (n = 8) or by pretreatment with R892 (0.1 μM) (n = 7) or with indomethacin (3 μM) (n = 6), a B1 receptor antagonist and a COX inhibitor, respectively. The B1 receptor selective agonist kallidin (0.1 nM–3 μM) failed to increase the smooth muscle basal tension (n = 6) or inhibit the U46619-induced tone (n = 7).

Effect of Extracellular Ca2+ Removal and VOC (L-Type) and Non-VOC Channel and Rho/Rho-Kinase Pathway Blockade on BK Contractions

Extracellular Ca2+ removal reduced the response evoked by 3 μM BK (contractions of 61 ± 9% and 3 ± 1% of the KPSS-induced tone, in the presence and absence, respectively, of

Fig. 1. (A) Western blot of pig intravesical ureter membranes from smooth muscle (M) and urothelium (U) incubated with a bradykinin (BK) B2 receptor antibody, showing a 43 kDa major band corresponding to the expected molecular weight for B2 receptor, both in smooth muscle and urothelium (Fig. 1A). Moreover, BK receptor subtype antibodies combined with the neuronal marker PGP 9.5 showed B2 receptor expression within nerve fibers distributed in the smooth muscle layer of the intravesical ureter, running parallel to the smooth muscle bundles (n = 5) (Fig. 1B–I). B1 receptor expression was not detected.

Neurourology and Urodynamics DOI 10.1002/nau
extracellular Ca$^{2+}$, *P* < 0.05, paired *t*-test, *n* = 7) (Fig. 3A and B). Nifedipine (1 μM, *n* = 6) and SKF96365 (10 μM, *n* = 6), inhibitors of VOC (L-type) and non-VOC channels, respectively, potently reduced BK contractions (Fig. 3D). Pretreatment with nifedipine plus SKF96365 evoked a similar inhibition to that produced by nifedipine alone (*n* = 8) (Fig. 3C and D). Y27632, a selective inhibitor of the Rho-associated protein kinase, did not change the BK contractions (*n* = 6).

**Effect of B$_1$ and B$_2$ Receptor Blockade on NANC Neurogenic Relaxations**

To investigate the role of BK receptors in NANC inhibitory neurotransmission, intravesical ureter strips were pretreated with guanethidine and atropine, noradrenergic neurotransmission, and muscarinic receptor blockers, respectively, and contracted with the thromboxane analogue U46619 (0.1 μM).

*Neurourology and Urodynamics* DOI 10.1002/nau
Under these conditions, EFS (0.5–16 Hz) evoked frequency-dependent relaxations (maximal responses of 83 ± 5% at 16 Hz, n = 14 from nine pigs), which were reduced by HOE140 (0.1 μM, n = 8), a B2 receptor antagonist, in the absence (Fig. 4A and B) or presence (Fig. 4C) of the NO synthase inhibitor L-NOARG. Intravesical ureter neurogenic relaxations were unchanged by B1 receptor blockade (Fig. 4D, n = 6).

**DISCUSSION**

Our results provide morphological and functional evidence for an involvement of neuronal and smooth muscle B2 BK receptors in the regulation of muscle tension to the pig intravesical ureter. BK produces contraction via activation of smooth muscle B2 receptors essentially coupled to extracellular Ca2+ entry via L-type VOC channels. In addition, neuronal B2 receptors facilitating the NO-dependent and independent NANC inhibitory neurotransmission are also involved. This conclusion is supported by the following observations: (i) The presence of the B2 receptor in the smooth muscle and urothelium, as well as B2 receptor-IR detected within nerve fibers widely distributed in the muscle layer of the intravesical ureter; (ii) BK-induced contraction was profoundly reduced as a consequence of extracellular Ca2+ removal and by B2 receptor and L-type VOC channel blockade; and (iii) The NANC neurogenic relaxation elicited by EFS, in the absence or presence of NO synthase inhibitors, was reduced by B2 receptor selective blockade.

The autonomic nervous system plays an essential role in the maintenance of ureteral motor activity. Thus, noradrenaline and acetylcholine stimulate intravesical ureter phasic activity and basal tone through adrenergic and muscarinic, respectively, receptors. Nitric oxide (NO) and unknown nature mediator/s are involved in the non-adrenergic non-cholinergic (NANC) inhibitory neurotransmission of the pig intravesical ureter. Peptides as substance P or neurokinin A evoke a direct contraction through smooth muscle NK1 receptors, whereas vasoactive intestinal peptide (VIP) or pituitary adenylate cyclase-activating polypeptide 38 (PACAP 38) relax the intravesical ureter through smooth muscle VIP/PACAP receptors.

In the current study, BK evoked a potent contraction on ureteral strip basal tension, which was not changed as a consequence of urothelium mechanical removal, thus suggesting the involvement of smooth muscle receptors in such a response. This was also suggested by the Western blot and immunostaining of intravesical ureter samples showing a B2 receptor expression throughout the smooth muscle layer, which agrees with the B2 receptor-IR described in the pig bladder neck. BK is an endogenous kinin receptor agonist that displays selectivity for B2 over B1 receptors. This together with the facts that the B1 receptor selective agonist kallidin failed to modify the preparations basal tone and that the B1 receptor expression was not detected, suggested the mediation of smooth muscle B2 receptors in intravesical ureter BK-elicited contractions. The involvement of this BK receptor is also supported by the inhibition produced by HOE140, a B2 receptor selective antagonist, on BK contractile responses. This antagonist shifted the BK CRC to the right in a non-competitive manner, which may be explained in terms of the presence of neuronal B2 receptors mentioned above or alternatively by the

contribution of a heterogeneous BK receptor population in the BK-elicited contraction. The lack of effect of kallidin on basal tension and of R892, a B2 receptor selective antagonist, on BK contractions ruled out a possible role for B2 receptors. The fact that the BK contraction was not modified as consequence of urotheleium removal suggested a lack of contractile effect mediated via a urothelial B2 receptor subtype, which agrees with those found in the bladder neck.10 B2 receptors have previously been reported to promote proliferation of human prostate stromal cells via activation of ERK-1/2 pathways.22 In the current study, since urothelial B2 receptors are not involved in the regulation of the smooth muscle tension, their role might possibly be ascribed to proliferative actions.

During the filling phase, the bladder shows local contractions produced by a basal myogenic mechanical activity that may be increased by the local release of COX-derived prostanoids and these spontaneous contractions are able to generate activity in afferent nerves that may contribute to detrusor overactivity.23 In our study, however, indomethacin, a COX inhibitor, failed to modify BK-elicited responses, thus indicating that COX pathway-derived prostanoids are not involved in BK contractions.

In the bladder, receptor-mediated contraction is largely dependent on extracellular Ca2+ entry via dihydropyridine-sensitive L-type Ca2+ channels.24 In the current investigation, the potent reduction of the BK-induced contraction obtained in a Ca2+-free PSS, or by pre-treatment with nifedipine, a L-type VOC channel blocker, suggests that BK contractions occur through Ca2+ influx via L-type Ca2+ channel-dependent mechanisms. In addition, a non-L-type Ca2+ entry mechanism also contributes to the BK-elicited contraction. This mechanism could include voltage-gated channels, such as T- or P/Q-type channels, and/or voltage-independent store- and receptor-operated channels.10 In the intravesical ureter, the inhibition produced by the Ca2+ entry inhibitor SKF96365, indicates that other Ca2+ channels different from the L-type Ca2+ may also be involved in BK-induced Ca2+ entry. The slight contraction exhibited by submaximal BK concentrations in a Ca2+-free medium suggests that a consistent intracellular Ca2+ mobilization is not likely to be involved. Bladder contractility is partly independent of changes in intracellular Ca2+ concentration via a Rho/Rho-kinase pathway and myosin phosphatase inhibition.25 In the current study, Y27632, a selective inhibitor of the Rho-associated protein kinase, failed to modify the BK contraction, which seems to rule out the possible involvement of a Rho/Rho-kinase pathway in such an effect.

In the pig intravesical ureter, both NO-dependent and independent NANC inhibitory neurotransmission has been demonstrated.18 Thus, neuronal-released NO relaxes smooth muscle through a guanylyl cyclase-dependent mechanism involving KATP channel activation.19 In this structure, neuronal peptidergic receptors have been identified as modulating the release of inhibitory transmitters. Thus, facilitatory PAC1 receptors located at capsaicin-sensitive primary afferents and coupled to NO release, and inhibitory VPAC receptors at motor neurons are involved in the relaxations to PACAP 38 and VIP, respectively.21 For this reason, we investigated the possible modulatory role exerted by kinin receptors on NANC inhibitory neurotransmission. In the present study, B2 receptor IR was also observed within nerve fibers among smooth muscle bundles, and the B2 receptor antagonist HOE140 reduced both NO-dependent and independent neurogenic relaxations. These results suggest the presence of a neuronal B2 receptor population stimulating the release of NO and other/s inhibitory neurotransmitters in the intravesical ureter.

BK receptors have been proposed as therapeutic targets for stress urinary incontinence.11 The fact that pre- and post-junctional B2 receptors regulate intravesical ureter smooth muscle tension raises the possibility that these receptors might also be considered as pharmacological targets for the treatment of vesicoureteral reflux.

CONCLUSIONS

The present results suggest that BK elicits contraction of the pig intravesical ureter through smooth muscle B2 receptors essentially coupled to extracellular Ca2+ entry mainly via VOC (L-type) channels. Neuronal facilitatory B2 receptors modulating NO-dependent or -independent inhibitory neurotransmission have also been shown (Fig. 5).
